Determinants of Inequality in Selected SEE Countries:
Results from Shapley Value Decompositions

The wiiw Balkan Observatory

www.balkan-observatory.net

About

Shortly after the end of the Kosovo war, the last of the Yugoslav dissolution wars, the Balkan Reconstruction Observatory was set up jointly by the Hellenic Observatory, the Centre for the Study of Global Governance, both institutes at the London School of Economics (LSE), and the Vienna Institute for International Economic Studies (wiiw). A brainstorming meeting on Reconstruction and Regional Co-operation in the Balkans was held in Vouliagmeni on 8-10 July 1999, covering the issues of security, democratisation, economic reconstruction and the role of civil society. It was attended by academics and policy makers from all the countries in the region, from a number of EU countries, from the European Commission, the USA and Russia. Based on ideas and discussions generated at this meeting, a policy paper on Balkan Reconstruction and European Integration was the product of a collaborative effort by the two LSE institutes and the wiiw. The paper was presented at a follow-up meeting on Reconstruction and Integration in Southeast Europe in Vienna on 12-13 November 1999, which focused on the economic aspects of the process of reconstruction in the Balkans. It is this policy paper that became the very first Working Paper of the wiiw Balkan Observatory Working Papers series. The Working Papers are published online at www.balkan-observatory.net, the internet portal of the wiiw Balkan Observatory. It is a portal for research and communication in relation to economic developments in Southeast Europe maintained by the wiiw since 1999. Since 2000 it also serves as a forum for the Global Development Network Southeast Europe (GDN-SEE) project, which is based on an initiative by The World Bank with financial support from the Austrian Ministry of Finance and the Oesterreichische Nationalbank. The purpose of the GDN-SEE project is the creation of research networks throughout Southeast Europe in order to enhance the economic research capacity in Southeast Europe, to build new research capacities by mobilising young researchers, to promote knowledge transfer into the region, to facilitate networking between researchers within the region, and to assist in securing knowledge transfer from researchers to policy makers. The wiiw Balkan Observatory Working Papers series is one way to achieve these objectives.

The wiiw Balkan Observatory

Global Development Network Southeast Europe

This study has been developed in the framework of research networks initiated and monitored by wiiw under the premises of the GDN–SEE partnership.

The Global Development Network, initiated by The World Bank, is a global network of research and policy institutes working together to address the problems of national and regional development. It promotes the generation of local knowledge in developing and transition countries and aims at building research capacities in the different regions.

The Vienna Institute for International Economic Studies is a GDN Partner Institute and acts as a hub for Southeast Europe. The GDN–wiiw partnership aims to support the enhancement of economic research capacity in Southeast Europe, to promote knowledge transfer to SEE, to facilitate networking among researchers within SEE and to assist in securing knowledge transfer from researchers to policy makers.

The GDN–SEE programme is financed by the Global Development Network, the Austrian Ministry of Finance and the Jubiläumsfonds der Oesterreichischen Nationalbank.

Abstract

In this paper we provide a comparative analysis of inequality in household consumption per capita in four South-Eastern European countries, Albania, Bosnia & Herzegovina, Bulgaria, and Serbia. The analysis is based on a largely consistent dataset derived from the World Bank's Living Standards Measurement Study (LSMS) providing data for at least two years for each of these countries and a comparable set of variables. We apply inequality decomposition methods based on regression analysis and variants of the Shapley value approach. We also present results from related methods like a decomposition of the explained variance using different approaches for comparisons. The results suggest that three groups of variables are particularly important for explaining patterns of inequality; these are socio-demographic variables, employment status and education. Regional aspects and nationality or ethnicity plays a less important role though there are some country differences.

DETERMINANTS OF INEQUALITY IN SELECTED SEE COUNTRIES: RESULTS FROM SHAPLEY VALUE DECOMPOSITIONS

SEBASTIAN LEITNER AND ROBERT STEHRER

1 Introduction

This paper is concerned with determinants of inequality in a sample of Western Balkan countries (Albania, Bulgaria, Bosnia & Herzegovina and Serbia). To our knowledge this is the first attempt to provide a comparative analysis for this set of countries based on individual or household data.¹ Using data from the World Bank's Living Standards Measurement Study (LSMS), described below in more detail, we analyse determinants of inequality with respect to consumer units (e.g. households). In particular we provide decomposition results from regression based methods partly based on the Shapley value approach. The literature on comparative studies of income inequality in transition economies and on Western Balkan countries in particular is rather scarce (see however Milanovic, 1999, analysing inequality with focus on inequality by income sources). In this sense the paper contributes to the literature in providing evidence on this region based on comparable data and using a method which allows for such a cross-country approach.

Before starting let us however present some inequality trends in the countries under consideration using already existing databases. Table 1.1 present available information on Gini coefficients from the WIDER database.² This is based on household data with consumption, expenditures or disposable income per capita (i.e. no equivalence scales were used). The Gini coefficients on consumption expenditures are available for Albania, Bulgaria and Bosnia & Herzegovina. For Albania the Gini is rising from about 29 in 1996 to about 31 in 2004; similarly for Bulgaria the Gini was rising from 28 (in 1998) to a level of about 31 in 2001. Bosnia & Herzegovina experienced the strongest increase from 26 in 2001 to 36 in 2005.³ For Serbia the Gini coefficient based on disposable income per capita is higher with about 40 in 2003 but even slightly declining over time.⁴ With respect to the levels compared to other country groups the Gini coefficient is

¹There are however individual country studies; e.g. INSTAT (2006) and Canova (2006) on Albania.

²See <http://www.wider.unu.edu>.

³For Bulgaria also other income or expenditure definitions would be available. In all cases these show increasing trends.

⁴The Gini coefficient based on personal earnings data increasing slightly from 31 to a level of about 35 in 2006.

Country	Income/Expenditure definition	Year	Gini (1)	Gini (2)
Albania	Consumption	1996	29.3	28.0
		2002	28.1	28.2
		2004	31.1	31.1
Bulgaria	Consumption	1995	28.0	29.2
		1997	30.0	32.1
		2001	30.6	32.2
Bosnia & Herzegovina	Consumption	2001	26.0	26.2
		2005	35.8	35.8
Serbia	Disposable Income	2003	40.3	40.3
		2004	39.3	39.3
		2005	39.3	39.3
		2006	38.8	38.8

Notes: Gini (2) reports a Gini coefficient adjusted by WIDER.

Table 1.1: Gini coefficients from WIDER database (households)

slightly above those for Western Europe and Central and European countries on average, but lower compared to other country groups (like Russia, CIS countries, East Asian countries, etc.).

In this paper we are mainly interested in the determinants of these inequality levels in the four Western Balkan countries. The aim of this research was to set up a rather consistent dataset allowing for a comparison across countries. Further, from a methodological point of view, we applied existing decomposition methods based on regression approaches. In Section 2 we briefly discuss the data we use in this paper and point to several constraints and problems regarding data availability and quality. We further provide evidence on inequality measures using this dataset. In Section 3 we present the results of a decomposition analysis based on regressions combined with the Shapley value approach. We also compare the results to some alternative - however related - calculations. In this section we mainly draw on existing techniques and therefore keep the technical descriptions to a minimum however providing references to the literature. Section 4 concludes.

2 Data and descriptive evidence

2.1 Data sources

In this study we use data collected from the The World Bank's Living Standards Measurement Study (LSMS). The datasource (LSMS) is well described and explained in detail in Deaton (1997) also pointing towards potential problems and pitfalls. From this data source we collected

information which is available across countries to allows for cross-country comparisons. The countries, years and variables chosen are mainly dictated by the availability of comparable data. Of course, this reliance on LSMS data has some drawbacks as the surveys are not intended for cross country comparisons. However, we do think that the variables we are focusing on and the method applied for decomposition gives allows such a comparison. Furthermore, one has to have in mind that the structure of the available data sets implies that the data have to be collected separately for each country and the years for which data are available differ across countries. Table 2.1 provides an overview of the data coverage. Accordingly, we have been

Country	Years	
Albania	2002, 2005	Consumption
Bulgaria	1995, (1997), 2001	Consumption, Income
Bosnia & Herzegovina	2001, 2004	Consumption
Serbia	2002, 2007	Consumption, Income

Table 2.1: Data coverage

successful to establish a more or less comparable database for four Western Balkan countries, i.e. Albania, Bulgaria, Bosnia & Herzegovina and Serbia. As one can see the years for which the LSMS was conducted differs across countries. Whereas for Bulgaria the survey data are available for 1995 and 2001, these are available for more recent years in the other countries, namely for 2002 or 2005 for Albania, for 2001 and 2004 for Bosnia & Herzegovina, and 2002 and 2007 for Serbia, respectively.⁵ With respect to the income variable we decided to use household consumption rather than income data which seems to be more reliable. The drawback on using household consumption data is that we can employ only information about the characteristics of the household head. For this we collected information by sex ('Male' and 'Female'), age groups (<25, 25-34, 35-44, 45-54, 55-64, 65-74, >=75), education (None, low, medium, uppers secondary and tertiary), nationality or ethnical groups, regional classification and employment status of the household head (employed, employer, unemployed, retired and others). Unfortunately, these information is not fully available for all countries and years. Information on nationality/ethnicity is missing for Bosnia & Herzegovina and for Serbia in 2002. From these data we calculated

⁵For some countries - Bulgaria (1995 and 1997) and Albania (2002,2003, and 2004) - a panel structure might be exploited which would allow to control for unobserved heterogeneity in regression analysis. however, as we wanted to compare a broader set of countries we have not yet used this possibility.

household consumption per capita per month (i.e. dividing the total consumption with the number of persons; further we also use a second measure by applying an equivalence scale, total consumption divided by the square root of the number of persons, i.e. we assume an equivalence parameter of $\rho = 0.5$ which is commonly used in the literature. Further, for being able to compare data across countries we converted household consumption using purchasing power parity rates (PPPs) for the respective years. One should note that this transformation does not change the inequality measures provided below.

2.2 Summary statistics and inequality measures

Before presenting the results of the decomposition analysis we shortly present simply summary statistics for each of the countries under consideration based on the collected data. The widely used inequality measures are well documented and explained in a number of papers and books, notably Jenkins (1995) and Sen (1997). In more global context these methods are applied in Milanovic (2005); for an overview see Anand and Segal (2008). In this paper we use the most common ones, the mean logarithmic deviation (MLD or I_0), the Theil measure (I_1), and the half squared coefficient of variation (I_2); formally, $I_0 = \frac{1}{N} \sum_{i=1}^N \ln \frac{\mu}{y_i}$, $I_1 = \frac{1}{N} \sum_{i=1}^N \frac{y_i}{\mu} \ln \frac{y_i}{\mu}$, and $I_2 = \frac{1}{2} \cdot \frac{1}{N} \sum_{i=1}^N \left[\left(\frac{\mu}{y_i} \right)^2 - 1 \right] = \frac{1}{2} \cdot \frac{\sigma^2}{\mu^2}$. Here, N denotes the number of units (individuals, households), y_i is the income or expenditure category, $\mu = \frac{1}{N} \sum_{i=1}^N y_i$ denotes the mean income or expenditure, and σ denotes the variance. These are special cases of the generalized class of entropy measures, defined as

$$I_\alpha = \frac{1}{\alpha(1-\alpha)} \frac{1}{N} \sum_{i=1}^N \left[1 - \left(\frac{y_i}{\mu} \right)^\alpha \right] \quad \text{for } \alpha \neq 0, 1.$$

For $\alpha = 0$ this becomes Theil's 'second' measure (the mean logarithmic deviation or I_0) and for $\alpha = 1$ the Theil measure I_1 . These measures are mainly used as they possess favorable decomposition probabilities (see e.g. Sen, 1997, for a summary and details). Further we present the Gini index (G) given by

$$G = \frac{N+1}{N-1} - \frac{2}{N(N-1)\mu} \sum_{i=1}^N \rho_i y_i.$$

In this formula ρ_i denotes the rank of unit i in the distribution; the counting is from the top such that the richest unit has rank 1.⁶

Table 2.2 presents the mean of household consumption per capita and the respective inequality measures for the data not applying and applying the equivalence scale.⁷ Starting with the

Country	Year	Mean	I_0	I_1	I_2	Gini
No equivalence scale ($\rho = 1$)						
Albania	2002	158.7	0.137	0.140	0.166	0.290
	2005	177.5	0.158	0.166	0.213	0.311

	2004	684.9	0.095	0.096	0.108	0.246
Serbia	2002	554.3	0.171	0.176	0.223	0.320
	2007	717.5	0.158	0.163	0.204	0.309

Table 2.2: Sample inequality measures

Gini coefficient one can see that this is roughly in line with the values reported in Table 1.1 above with values being around 30.⁸ For this sample, in Albania and Bulgaria the Gini and inequality measured by the other coefficients was increasing over time; in Bosnia & Herzegovina and Serbia the inequality measures were decreasing. One should note that the levels of the inequality measures are not strictly comparable in terms of levels which mainly reflect their respective properties (see e.g. Sen, 1997). In most countries the mean income in the sample was increasing; the

⁶The formula is equivalent to the more commonly known expression $G = \frac{1}{\mu N(N-1)} \sum_{i>j} \sum_j |y_i - y_j|$ which however is computationally less convenient.

⁷In the Appendix we provide further detailed results with respect to household characteristics.

⁸The values for Serbia are not strictly comparable as in 1.1 these are based on disposable income.

only exception being Bosnia & Herzegovina. When applying an equivalence scale of $\rho = 0.5$ the mean income is increasing as expected. There is however no clear tendency with respect to the inequality measures: These are lower in Albania, Bosnia & Herzegovina, and Serbia but slightly higher Bulgaria.

3 Determinants of inequality

In this section we present results from a decomposition analysis to explain the sources of income inequality by the characteristics of households ('income recipients approach'). The method chosen in this paper is based on regression analysis and the Shapley value approach. In the next subsection we provide a simplified introduction to this method without going into technical details but referring to the relevant literature where these techniques are described in more detail. Similarly, we do not refrain the potential advantages and disadvantages of this method compared to the more classical decomposition methods of inequality measures which can be found in the literature. This is followed by a presentation of the respective results.

3.1 The Shapley value approach to decomposition

Recently the literature has provided some additional decomposition methods which is based on regression results and the Shapley value approach as introduced by Shorrocks (1999) in the inequality literature; see Fields and Yoo (2000), Morduch and Sicular (2002), Fields (2003), Wan (2004), and Gunatilaka and Chotikapanich (2006) for such applications; see also Cowell and Fiorio (2009) for a critical review. Finally, Israeli (2007) shows how the Shapley-approach is related to the method proposed by Fields (2003) and also points to some advantages of the former which is applied in this paper as well. The most important advantage of the Shapley value approach is that this take the potential correlation amongst regressors into account. One should however note that the latter two contributions aim at decomposing the R^2 of the regressions whereas in this paper we decompose the resulting inequality measure. This is more similar to the contributions by Wan (2004) Gunatilaka and Chotikapanich (2006).

We explain the Shapley value approach using a simple example with three explanatory variables. This low dimension is useful as it allows to introduce the idea in a simple way. Furthermore, below we use groups of variables (rather than individual variables) for the decomposition

analysis.⁹ We first regress consumption levels y_i on these explanatory variables x_i ($i = 1, 2, 3$),

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \varepsilon$$

where ε denotes the error term. The predicted consumption level is then given by

$$\hat{y}_{123} = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \hat{\beta}_2 x_2 + \hat{\beta}_3 x_3.$$

This predicted value is then used to calculate the Gini coefficient $\hat{G}_{\{123\}}^{(0)}$, where subscripts denote the variables included. In the first round we then eliminate one variable and calculate the predicted consumption levels $\hat{y}_{\{23\}}$, $\hat{y}_{\{13\}}$ and $\hat{y}_{\{12\}}$. The corresponding Gini coefficients are then given by $\hat{G}_{\{23\}}^{(1)}$, $\hat{G}_{\{13\}}^{(1)}$ and $\hat{G}_{\{12\}}^{(1)}$ respectively. Analogously, in the second round we eliminate two variables, thus calculating $\hat{y}_{\{1\}}$, $\hat{y}_{\{2\}}$ and $\hat{y}_{\{3\}}$. The resulting Gini coefficients are $\hat{G}_{\{1\}}^{(2)}$, $\hat{G}_{\{2\}}^{(2)}$ and $\hat{G}_{\{3\}}^{(2)}$. The final round would then be to only include the constant; the resulting Gini coefficient would thus be $\hat{G}_{\{\}}^{(3)} = 0$.

The marginal contributions are then calculated using the Gini coefficients. The first round marginal contribution of each variable are $C_1^{(1)} = \hat{G}_{\{123\}}^{(0)} - \hat{G}_{\{23\}}^{(1)}$, $C_2^{(1)} = \hat{G}_{\{123\}}^{(0)} - \hat{G}_{\{13\}}^{(1)}$ and $C_3^{(1)} = \hat{G}_{\{123\}}^{(0)} - \hat{G}_{\{12\}}^{(1)}$. The marginal contributions in the second round of the first variable are given by

$$C_1^{(2,1)} = \hat{G}_{\{12\}}^{(1)} - \hat{G}_{\{2\}}^{(2)} \quad \text{and} \quad C_1^{(2,2)} = \hat{G}_{\{13\}}^{(1)} - \hat{G}_{\{3\}}^{(2)}.$$

The average of these contributions is then marginal contribution of the first variable in the second round, i.e. $C_1^{(2)} = \frac{1}{2}(C_1^{(2,1)} + C_1^{(2,2)})$. Similarly, we calculate $C_2^{(2)}$ and $C_3^{(2)}$. The third round contribution then is given by $C_1^{(3)} = \hat{G}_{\{1\}}^{(2)} - \hat{G}_{\{\}}^{(3)} = \hat{G}_{\{1\}}^{(2)}$ as $\hat{G}_{\{\}}^{(3)} = 0$ and analogously for $C_2^{(3)} = \hat{G}_{\{2\}}^{(2)}$ and $C_3^{(3)} = \hat{G}_{\{3\}}^{(2)}$.

Finally, by averaging the marginal contributions of each variables over all rounds results in the total marginal effect of each variable $j = 1, 2, 3$, i.e.

$$C_j = \frac{1}{3} \cdot (C_j^{(1)} + C_j^{(2)} + C_j^{(3)}).$$

The proportion of inequality not explained is then given by

$$C_R = G - \hat{G}_{\{123\}}^{(0)}.$$

The approach can be easily extended to any number of explanatory factors and to other inequality measures as we will show below.

⁹One could then go a step further and apply a hierarchical analysis within these groups of variables which however is not done in this paper focusing on cross country differences or similarities in broader categories.

3.2 Results

Based on this approach we first regressed household consumption expenditures on a number of variables including age, sex, employment status categories, regional dummies, educational categories and nationality or ethnicity. The exact variables used differ somewhat across countries and we report the underlying regression results in Appendix Tables B.1 to B.4. The explained part of the variance is about 20 % reported as the R^2 in these tables. The signs of the coefficients are in most cases in line with the expectations however in a low number of cases are counterintuitive.¹⁰

The results from the inequality decomposition using the Shapley value approach are reported in Tables 3.1 to 3.4 for the four countries respectively. For each country we present the results for the three measures of inequality introduced above (Gini, I_0 and I_2), and for household consumption per capita and equivalent household income (with $\rho = 0$). These tables present

¹⁰We also experimented on various transformations of the data by using logarithms for example. Wan (2004) suggested to transform the data using Box-Cox or Box-Tidwell transformations. We also tried to use to use quantile estimation which is more robust to outliers. However this did not improve the results a great deal and when doing the decomposition analysis results are similar to those reported on the regressions reported.

Table 3.4: Shapley value decomposition: Serbia

properties: First, the contributions in absolute values sum up to the overall inequality measure reported in Table 2.2 due to the decomposability property of the Shapley value. Second, regarding results for the three inequality measures one can see that the unexplained part of inequality is much larger for the generalized entropy measures I_0 and I_2 compared to the Gini coefficient. For the latter the unexplained part is around 50 %. This is remarkable as the R^2 reported in the regressions ranges between 20 and 30 % in most cases. The explanation for this is likely to be that the OLS regression (on the untransformed data) does not very well predict the values at the tails of the distribution (which is likely to be more relevant for the entropy measures). For these reasons we thus focus on the results based on the Gini coefficient. Third, the contributions to inequality can seemingly be negative which is a critical point referred to in the literature. In the next section below we therefore present results from alternative approaches (but still based on the Shapley value) which circumvent this problem.

For *Albania* education and ethnicity explains the largest part of inequality in 2002 with 11 and 13.6 % respectively. However, there is a remarkable shift towards inequality explained mainly by age and sex (16.8 %), region (11.6 %) and education (15.1 %) in 2005.¹¹ The results when applying equivalence scaling give with 19.3 % much more explanatory power to the employment

¹¹The summary statistics in the Appendix show a large increase in one region which might also point towards a data problem. Further, the number of for other ethnical groups are quite small.

status in both years; education is however the most important source of inequality with more than 20 %. The regional aspect again becomes important in 2005 only. For *Bosnia & Herzegovina* in the case of no equivalence scale applied age and sex together with employment status are the most important sources of inequality (explaining about 35 % in 2001 and almost 50 % in 2004 when taken together) with education playing a less important role with about 10 % and 5 % respectively. However, when applying the equivalence scaling employment status (22 and 24.2 %) and education (24.5 and 16.8 %) make up the largest part in the explanation. In *Bulgaria* again employment status (27.8 %) and education (17.2 %) are the most important variables in 1995; however, in 2001 it is age and sex together with employment status (with 27.6 and 18.5 %, respectively). In this case the results are similar when using the scaled consumption data. Finally, for *Serbia* in both cases and both years age and sex (22 and 24.6 % in both years) and education (23.1 and 28.2 %) are the most important determinants of inequality with only little changes for the two years.

Summarizing, the results suggest a dominant role for basically three variables: age and sex, employment status and education though in most cases only two of these account for almost half of the explained inequality measured by the Gini coefficient. This pattern is however not stable over years for which data are available and also differ when applying an equivalence scale. In a technical sense this could point towards either problems with the underlying data, the survey itself, or changes in correlations amongst the explanatory variables. Ethnicity and regional aspects only play a minor role in explaining inequality from these results.

3.3 Comparisons to alternative decomposition methods

As mentioned above there are also some alternative methods to decompose the explained part of income or consumption equations. We now presents results from such alternatives and compare them with the findings reported above. First, we consider the method as proposed by Fields (2003) who suggested to decompose the R^2 by exploiting

$$Var(y) = \sum_{j=1}^J Cov(\hat{\beta}_j x_j, y) + Cov(e, y).$$

Dividing the r.h.s. by $Var(y)$ provides the relative contributions.

Israeli (2007) shows that this decomposition can be seen as a special case of a Shapley decomposition of the R^2 . In fact, Israeli (2007) proposes two different methods to calculate

the Shapley decomposition. The first is based on a single regression but calculating the various explained parts by using subsamples of variables only. The second method requires to estimate of a number of regressions (depending on the number of potential elimination sequences) which differ by the set of variables included. In both cases the problem that the elimination sequence matters is circumvented by averaging over all possible elimination sequences as suggested by Shorrocks (1999).

In the Appendix Tables C.1 to C.4 we present the results from these three exercises for three countries, respectively. In the columns denoted 'Shapley on Gini' we included the results from the decomposition of the Gini coefficient as reported above. In these tables we however present the explained part of the Gini coefficient and the contributions of the particular factors as share of this explained part. The last two columns provide results from a Shapley value decomposition on the Gini index based on many regressions which can be seen as a direct alternative to the approach taken above.

Figures 3.1 to 3.4 present an overview of the results with respect to the explained part of the variance or the inequality measure, respectively. The first set of bars ('Fields method',

Figure 3.1: Albania

Figure 3.2: Bosnia & Herzegovina

Figure 3.3: Bulgaria

Figure 3.4: Serbia

'Fields-Shapley 1' and Fields-Shapley 2') present the results from the Fields method and the ones suggested by Israeli (2007) mentioned above. In most cases there is only little variation with respect to the parts explained by particular (groups of) variables. This is particularly the case for Albania, Bulgaria and Serbia but less so for Bosnia & Herzegovina. This might not be surprising as it is still a decomposition of the R^2 of the underlying regression rather than a decomposition of the inequality measure. The results for the latter are reported in the last two sets of bars ('Shapley on Gini' and 'Shapley JReg on Gini'). Here the differences are compared to the decomposition of the R^2 is larger; however the decomposition of the Gini using many regressions seems to be more in line with those of the decomposition of the R^2 . It might be interesting to note that most of the difference in explanatory power of the Shapley value approach to the Gini based on one regression and the others is mostly due to a higher share of explanatory variables comprising age and sex. Furthermore, the methods decomposing the R^2 and the Shapley decomposition using many regressions are more stable over the years available.

With respect to the question which explanatory variables account for mostly for explaining the inequality however the result is again that education and employment status matter most

across countries though the exact share differ with respect to the method chosen. Age and sex is the third most important characteristics followed by region in all countries except Bulgaria. For this country nationality/ethnicity seems to be more important.

4 Conclusions

In this paper we provide evidence on the determinants of inequality with respect to consumption by households for four Southern and Eastern European countries: Albania, Bulgaria, Bosnia & Herzegovina, and Serbia. For this we used data collected from the LSMS database provided by the World Bank. We used decomposition methods based on regression analysis and Shapley value to consider inequality determinants by household characteristics. The results from the Shapley value approach suggest that mainly three groups of variables - age and sex, employment status and education - are the most important determinants. Somewhat surprisingly regional and nationality/ethnicity aspects play less important role in most cases. The latter variable is only relatively important in Bulgaria. These broader conclusions are roughly confirmed when using different decomposition methods and procedures; however the exact magnitudes can differ.

To our knowledge this paper is the first attempt to study determinants of inequality in these countries in a comparative manner using recent methodological techniques. Further the paper also provided a comparison of methods with respect to decomposition analysis in applied work. Finally, it also showed that such decomposition methods can fruitfully be applied in cross-country comparisons where similar data and explanatory variables are available.
